Scientists have a moral obligation to clearly warn humanity of any catastrophic threat and to “tell it like it is.” On the basis of this obligation and the graphical indicators presented below, we declare, with more than 11,000 scientist signatories from around the world, clearly and unequivocally that planet Earth is facing a

Climate tipping points – too risky to bet against

Timothy M. Lenton, Johan Rockström, Owen Gaffney, Stefan Rahmstorf, Katherine Richardson, Will Steffen & Hans Joachim Schellnhuber

The growing threat of abrupt and irreversible climate changes must compel political and economic action on emissions.

Politicians, economists and even some natural scientists have tended to assume that tipping points¹ in the Earth system – such as the loss of the Amazon rainforest or the West

assuming that climate tipping points are of very low probability (even if they would be catastrophic), have suggested that 3 °C warming is optimal from a cost–benefit perspective. However, if tipping points are looking more likely, then the ‘optimal policy’ recommendation of simple cost–benefit climate-economy models⁴ aligns with those of the recent IPCC report². In other words, warming must be limited to 1.5 °C. This requires an emergency response.

FEATURE

A safe operating space for humanity

Identifying and quantifying planetary boundaries that must not be transgressed could help prevent human activities from causing unacceptable environmental change, argue **Johan Rockström** and colleagues.

Rockström et al., 2009

Figure 1 | Beyond the boundary. The inner green shading represents the proposed safe operating space for nine planetary systems. The red wedges represent an estimate of the current position for each variable. The boundaries in three systems (rate of biodiversity loss, climate change and human interference with the nitrogen cycle), have already been exceeded.

Terra senza effetto serra -18°C Con effetto serra naturale $+15^{\circ}\text{C}$

Tyndall† in particular has pointed out the importance of this question. It was chiefly the diurnal variations of the temperature that were lessened in this circumstance. Another side of the question that has attracted the attention of physicists, is this: Is the temperature of the ground in any way influenced by the presence of heat-absorbing gases in the atmosphere? Fouri maintained that the atmosphere acts like the glass of a house, because it lets through the light rays of the sun and retains the dark rays from the ground. This idea was elaborated by Pouillet; and Langley's recent researches led to the same conclusion, even though our atmosphere were perfectly clear. It would probably fall to -200°C .

Climate warming during the course of the twenty-first century is projected to be between 1.0 and 3.7 °C depending on future greenhouse gas emissions, based on the ensemble-mean results of state-of-the-art Earth System Models (ESMs). Just how reliable are these projections, given the complexity of the climate system? The early history of climate research provides insight into the understanding and science needed to answer this question. We examine the mathematical quantifications of planetary energy budget developed by Svante Arrhenius (1859–1927) and Guy Stewart Callendar (1898–1964) and construct an empirical approximation of the latter, which we show to be successful at retrospectively predicting global warming over the course of the twentieth century. This approximation is then used to calculate warming in response to increasing atmospheric greenhouse gases during the twenty-first century, projecting a temperature increase at the lower bound of results generated by an ensemble of ESMs (as presented in the latest assessment by the Intergovernmental Panel on Climate Change). This result can be interpreted as follows. The climate system is conceptually complex but has at its heart the physical laws of radiative transfer. This basic, or “core” physics is relatively straightforward to compute mathematically, as exemplified by Callendar’s calculations, leading to quantitatively robust projections of baseline warming. The ESMs include not only the physical core but also climate feedbacks that introduce uncertainty into the projections in terms of magnitude, but not sign: positive (amplification of warming). As such, the projections of end-of-century global warming by ESMs are fundamentally trustworthy: quantitatively robust baseline warming based on the well-understood physics of radiative transfer, with extra warming due to climate feedbacks. These

projections thus provide a compelling case that global climate will continue to undergo significant warming in response to ongoing emissions of CO_2 and other greenhouse gases to the atmosphere.

Introduction

Climate change is a major risk facing mankind. At the United Nations Climate Change Conference held in Paris at the end of last year, 195 countries agreed on a plan to reduce emissions of CO_2 and other greenhouse gases, aiming to limit global temperature increase to well below 2 °C (relative to pre-industrial climate, meaning a future warming of less than 1.4 °C because temperature had already increased by 0.6 °C by the end of the twentieth century). The link between CO_2 and climate warming has caught the attention of scientists and politicians, as well as the general public, via the well-known “greenhouse effect” (Figure 1). Solar radiation passes largely unhindered through the atmosphere, heating the Earth’s surface. In turn, energy is re-emitted as infrared, much of which is absorbed by CO_2 and water vapour in the atmosphere, which thus acts as a blanket surrounding the Earth. Without this natural greenhouse effect, the average surface temperature would plummet to about -21°C ,¹ rather less pleasant than the 14 °C experienced today.

The concentration of CO_2 in the atmosphere is increasing year on year as we burn fossil fuels, which enhances the natural greenhouse effect and warms the planet. To what extent, then, must CO_2 emissions be kept under control in order to restrict global temperature rise to within 2 °C? The projections of complex Earth System Models (ESMs) provide quantitative answers to this question. Run on supercomputers, these models integrate the many processes taking place in the atmosphere, on land and in the ocean. According to the Intergovernmental Panel on Climate Change (IPCC), the latest results of these models indicate

Consistent multidecadal variability in global temperature reconstructions and simulations over the Common Era

PAGES 2k Consortium*

Multidecadal surface temperature changes may be forced by natural as well as anthropogenic factors, or arise unforced from the climate system. Distinguishing these factors is essential for estimating sensitivity to multiple climatic forcings and the amplitude of the unforced variability. Here we present 2,000-year-long global mean temperature reconstructions using seven different statistical methods that draw from a global collection of temperature-sensitive palaeoclimate records. Our reconstructions display synchronous multidecadal temperature fluctuations that are coherent with one another and with fully forced millennial model simulations from the Coupled Model Intercomparison Project Phase 5 across the Common Era. A substantial portion of pre-industrial (1300–1800 CE) variability at multidecadal timescales is attributed to volcanic aerosol forcing. Reconstructions and simulations qualitatively agree on the amplitude of the unforced global mean multidecadal temperature variability, thereby increasing confidence in future projections of climate change on these timescales. The largest warming trends at timescales of 20 years and longer occur during the second half of the twentieth century, highlighting the unusual character of the warming in recent decades.

OIL & GAS SUPPLY AND STRANDED ASSET RISK

How does potential oil and gas supply compare to demand under different global warming outcomes?

B2DS demand

SDS demand

NPS demand

Production from new oil fields 2019-2040

The only way that fossil fuel companies can be "Paris-aligned" is to commit to not sanctioning projects that fall outside the remaining carbon budget constraint.

In the context of the energy transition towards a decarbonised economy, these potential fossil fuel developments risk destroying investor value as well as the climate.

Share of capital expenditure at risk of stranding in each scenario (2019-2030)

NPS

SDS

B2DS

60%

83%

1.5°C warming

In a 1.5°C world, no new oil & gas project would be compliant

If no CCS is assumed, 1.5°C warming is delivered by existing projects alone.

The oil and gas in projects that have already been sanctioned will take the world past 1.5°C, assuming carbon capture and storage remains sub-scale. Without a response sufficient to prematurely close existing projects, a warming of a warming of 1.5°C is already effectively locked in, and no new projects are compliant with the low end of the Paris goals.

Oil and gas companies have approved \$50 billion of investment since 2018 in major projects that undermine climate targets and threaten shareholder returns

\$2.2^{tn}
at risk
by 2030

Largest non-Paris compliant projects sanctioned by oil and gas majors since 2018

Carbon Tracker has identified \$50 billion of investment in 19 major projects that are not even consistent with a 1.7-1.8°C pathway and would require oil prices of nearly \$60 per barrel or more to deliver adequate returns. They include:

Resource theme	Project	IOC partners	2019-2030 capex	Country	Scenario compliant	
	LNG Canada T1, T2	Shell	\$13 bn	Canada	No	No
	Gorgon/Jansz Stage 2	Shell, Chevron, ExxonMobil	\$3.6 bn	Australia	No	No
	Aspen Phase 1	ExxonMobil	\$2.6 bn	Canada	No	No
	Amoca FFD	Eni	\$1.4 bn	Mexico	No	No
	Zinia 2	BP, ExxonMobil, Total, Equinor	\$1.3 bn	Angola	No	No

Investment decisions on a further \$21 billion in 12 projects inconsistent with a low-carbon world are due this year.

These projects represent an imminent challenge for investors and companies looking to align with climate goals.

Demand / global warming scenarios:
